# CONNA: Addressing Name Disambiguation on the Fly

# Bo Chen<sup>®</sup>, Jing Zhang<sup>®</sup>, Jie Tang<sup>®</sup>, *Senior Member, IEEE*, Lingfan Cai, Zhaoyu Wang, Shu Zhao<sup>®</sup>, Hong Chen, and Cuiping Li

Abstract—Name disambiguation is a key and also a very tough problem in many online systems such as social search and academic search. Despite considerable research, a critical issue that has not been systematically studied is *disambiguation on the fly*— to complete the disambiguation in the real-time. This is very challenging, as the disambiguation algorithm must be accurate, efficient, and error tolerance. In this paper, we propose a novel framework — CONNA — to train a matching component and a decision component jointly via reinforcement learning. The matching component is responsible for finding the top matched candidate for the given paper, and the decision component is responsible for deciding on assigning the top matched person or creating a new person. The two components are intertwined and can be bootstrapped via jointly training. Empirically, we evaluate CONNA on two name disambiguation datasets. Experimental results show that the proposed framework can achieve a 1.21-19.84 percent improvement on F1-score using joint training of the matching and the decision components. The proposed CONNA has been successfully deployed on AMiner — a large online academic search system.

15 Index Terms—Name disambiguation, joint model, multi-field multi-instance

TAME disambiguation, aiming at disambiguating who is 17 who, is one of the fundamental problems of the online 18 academic network platforms such as Google Scholar, Micro-19 soft Academic and AMiner. The problem has been exten-20 sively studied for decades [9], [13], [21], [35], [40], [42], [47] 21 and most of the works focus on how to group the papers 22 belonging to same persons together into a cluster from 23 scratch. However, online academic systems have already 24 maintained a huge number of person profiles, which are 25 made by the "from scratch" algorithms or human beings. 26 Out of the consideration of the computation and time cost 27 of the real systems, it is not practical to re-compute the clus-28 29 ters from scratch for the new arriving papers every day. We need a more effective way to deal with the problem of name 30 31 disambiguation on the fly.

This paper takes AMiner as the basis to explain how we deal with the name ambiguity problem when continuously updating persons' profiles. AMiner is a free online academic search and mining system [37], which has already extracted

133,204,120 researchers' profiles from the Web [36] and integrated with 263,781,570 papers from heterogeneous publication databases [47]. Currently, the newly arrived papers of 38 AMiner are more than 500,000 per month. How to correctly 39 assign these papers to the right persons in the system on the 40 fly is a critical problem for many upper applications such as 41 expert finding, academic evaluation, reviewer recommendation and so on. 43

Existing methods on addressing the similar problem of 44 anonymous author identification [2], [46], [50] are possible 45 solutions to continuously disambiguating papers on the fly. 46 However, they merely target at finding the top matched 47 person from all the candidates, but fail to deal with the situ- 48 ation when no right person exists, which is common in real 49 academic systems. For example, the papers published by 50 new researchers should not be assigned to any persons, as 51 their profiles have not been established by the system. Thus, 52 to assign a paper on the fly, we need to pay attention to not 53 only find the top matched candidate, but also identify 54 whether to assign the top matched candidate or create a 55 new person. In other words, we consider the absence of the 56 right person from the candidates to be a distinct candidate, 57 the so-called NIL candidate. Fig. 1 illustrates the problem to 58 be solved in the paper, where given a paper with an author 59 to be disambiguated, the returned right person can be a real 60 person or a non-existing candidate denoted as NIL. Actu- 61 ally, in AMiner, in addition to the "on-the-fly" assignment, 62 we also perform a "from scratch" algorithm to cluster "NIL" 63 papers into new profiles, and run an offline "checking" 64 algorithm to correct errors from historical profiles periodi- 65 cally. In general, AMiner performs a multi-strategy combin- 66 ing "from scratch", "on-the-fly" and "checking" together to 67 solve the complex continuous name disambiguation prob- 68 lem. In this paper, we only introduce the principle of "on- 69

Fig. 1. Disambiguation on the fly. Given a target paper with target author as "Yang Yang", we aim at searching for the right person of "Yang Yang" from the candidates, where the right person can be a real person or a non-existing candidate denoted as NIL.

the-fly" strategy under the assumption that the previously
built profiles are correct, where the errors of the profiles are
left to the "checking" strategy.

To tackle the problem, we first investigate how to find the 73 top matched candidate for a given target paper. Straightfor-74 wardly, we can use the traditional feature-engineering 75 methods to estimate the matching probability between each 76 candidate and the target paper, and then return the top 77 matched candidate. However, these methods are devoted to 78 exactly matching the tokens between a paper and a person, 79 which is too rigid and cannot handle the cases with similar 80 semantics but different tokens. The widely used representa-81 tion-based models [2], [46] can capture the soft/semantic 82 83 matches through learning low-dimensional dense embeddings, but they may contrarily hurt the performance of exact 84 85 matching due to the highly compressed embeddings. For example in Fig. 1, if only depending on the semantics of 86 87 learned embeddings, we can infer that both of the candidates are interested in social network mining. However, it is 88 apparent that the exact matches of the coauthor names or 89 words, e.g., "Jie Tang", "Juanzi Li", "social", "network" 90 between the target paper and the right person are more 91 than those of the wrong person. Thus, a challenge is posed: 92 how to capture both the exact matches and the soft matches in a 93 principled way? Simultaneously, the effects of different fields 94 are different. For example, the two matched coauthors in 95 96 the right person make it significantly more confident than the wrong person with only one matched coauthor, com-97 98 pared with the matches in other fields. Besides, each person publishes multiple papers, which also take different effects. 99 For example in Fig. 1, in the papers of the right person, the 100 effect of the second similar paper may be diluted by the first 101 irrelevant one if combining all papers. Thus, an effective way 102 103 to distinguish the effects of different fields of the attributes and different instances of the published papers is worth studying. 104

After obtaining the top matched candidate, we need to 105 decide whether to assign the top matched candidate or NIL 106 107 candidate to the target paper. The NIL problem is widely studied in entity linking, a similar problem that aims at link-108 ing the mentions extracted from the unstructured text to the 109 right entities in a knowledge graph. We can adopt the simi-110 lar idea to assign the NIL candidate to a target paper if the 111 score of the top matched person is smaller than a NIL 112 threshold [8], [32] or if the top matched person is predicted 113

as NIL by an additional classifier [27]. Essentially, the first 114 process of finding the top matched candidate tries to keep 115 the relative distances between the right and the wrong persons of each target paper, and the later process of assigning 117 the top matched candidate or not devotes to optimize the 118 absolute positions among top matched candidates of all target papers. Intuitively, the two processes can influence each 120 other, and the errors of each process can be corrected by 121 their interactions. However, *none of the existing NIL solutions* 122 *are aware of this and it is not clear how to correct the errors by the* 123 *interactions between the two processes*. 124

To this end, in AMiner, we propose a joint model 125 CONNA that consists of a matching component and a deci- 126 sion component to solve CONtinuous Name Ambiguity, 127 i.e., name disambiguation on the fly, where "on the fly" 128 emphasizes the solved problem in the paper is different 129 from name disambiguation "from scratch". In the model, 130 the matching component adopts an interaction-based deep 131 learning model plus a kernel pooling strategy to capture 132 both the exact and soft matches between a target paper and 133 a candidate person and also a multi-field multi-instance 134 strategy to distinguish the effects of different attributes and 135 different instances of papers. The decision component is 136 trained on the similarity embeddings learned by the match- 137 ing component, to further decide whether a top matched 138 person is the right person or not. In addition, the errors of 139 the proposed model can be self-corrected through jointly 140 fine-tune the two components by reinforcement learning. 141 To summarize, the main contributions include:

- We propose CONNA consisting of a multi-field 143 multi-instance interaction-based matching compo-144 nent and a decision component to address the prob-145 lem of continuous name disambiguation. With 146 jointly fine-tuning of the two components by reinforcement learning, the errors of the two components 148 can be self-corrected. 149
- Experimental results on two large name disambigua- 150 tion datasets show that CONNA compares favorably 151 decision accuracy (+1.21%-19.84% in terms of F1) and 152 matching accuracy (+ 3.80%-49.90% in terms of HR@1) 153 against the baselines methods. CONNA is deployed 154 on AMiner to assign papers on the fly now. All codes 155 and data used in the paper are publicly available.<sup>1</sup>

# 2 **PROBLEM FORMULATION**

157

We introduce the definitions and the problem in this 158 section.

- **Definition 1 Paper.** We denote a paper as p associated with 160 multiple fields of attributes, i.e.,  $p = \{A_1, \ldots, A_F\}$ , where 161  $A_f \in p$  represents the fth attribute such as authors' names and 162 affiliations, title, keywords, venue and so on. 163
- **Definition 2 Target paper-author pair.** Given a paper p 164 with one of its authors denoted by a, we define a target paperauthor pair as  $\langle p, a \rangle$ , where p is the target paper and a is the target author to be disambiguated. We abbreviate a target paperauthor pair as a target pair henceforth. 168

1. https://github.com/BoChen-Daniel/TKDE-2019-CONNA

Fig. 2. Distribution of the same-coauthor ratio and the corresponding matching performance. Yellow bar: Distribution of the same-coauthor ratio of the target pairs. Lines: HR@1 performances of different methods.

**Definition 3 Candidate Persons.** Given a target pair  $\langle p, a \rangle$ , the corresponding candidate persons C are those who are closely related to the target pair  $\langle p, a \rangle$ . Each candidate person  $c_l \in C$  is composed of multiple papers, i.e.,  $c_l = \{p_1, \ldots, p_{n_l}\}$ , where each paper  $p_t = \{A_1, \ldots, A_F\}$  and  $n_l$  is the number of papers published by  $c_l$ .

For a target pair  $\langle p, a \rangle$ , to find the right person from its 175 candidate persons C, a straightforward way is to compare 176 the coauthors' names of a in p with the coauthors' names of 177 each candidate person in  $C^2$ . The assumption is the more 178 overlaps between the coauthors' names, the more likely the 179 candidate is the right author of p. The similar idea is 180 adopted in [20], which found that if only using the users' 181 names, 56 percent same users with different accounts across 182 183 the social networks can be correctly linked together. However, how can the names take effect in identifying the right 184 person for the target pairs? 185

To answer the question, we collect 100,000 target pairs from AMiner. For each target pair  $\langle p, a \rangle$ , we collect its candidate persons (Cf. Section 3.1 for candidate generation details) and calculate the same-coauthor ratio

Same-coauthor ratio = 
$$\frac{\max_{c \in C} S_c - \operatorname{second}_{c \in C} S_c}{\max_{c \in C} S_c - \min_{c \in C} S_c},$$
 (1)

191

where  $S_c$  is the number of the same coauthors of a in p with the candidate c. Same-coauthor ratio reflects the gap between the most similar candidate and the second similar candidate. The denominator is to normalize the gap calculated for different candidate lists into the same scale. It will be easier to distinguish the right person from the other candidates when the same-coauthor ratio is larger.

Then we plot the distribution of the same-coauthor ratio for all the target pairs in Fig. 2, where *X*-axis indicates the same-coauthor ratio of a target pair, and *Y*-axis on the left denotes the proportion of the target pairs with a certain samecoauthor ratio. From the figure, we can see that although 62.72 percent target pairs have large same-coauthor ratios, there are still 14.59 percent target pairs having small samecoauthor ratios. The coauthor-related features will hardly 206 take effect when dealing with the target pairs with small 207 same-coauthor ratios. For these target pairs, it is also not easy 208 to leverage other features except the coauthor features. 209

To verify the above hypothesis, we estimate the probabil- 210 ity of matching each candidate person to the target pair by 211 GBDT based on several features such as the literal similari- 212 ties between the title, venue, or the affiliations of the target 213 pair and those of a candidate person besides the coauthor- 214 related features, then evaluate whether the top matched 215 candidate is the right person or not and show the evaluated 216 metric, top 1 Hit Ratio (i.e., HR@1 on the right Y-axis) for 217 different ranges of the same-coauthor ratio in Fig. 2. Clearly, 218 we can see that the performance of GBDT decreases dramat- 219 ically with the decrease of the same-coauthor ratio. The 220 evaluated HR@1 is 66.71 percent when the same-coauthor 221 ratio is within (0, 0.1), but is 96.40 percent within (0.9,1.0). 222 The results indicate that when the coauthors of the target 223 pair and the right person are not similar, it is also difficult 224 for feature-engineering methods to capture the similarities 225 of other attributes. Thus, a more promising way to match 226 each candidate with the target pair is required. 227

In addition to find the top matched candidate, we also 228 need to consider the situation when no right person exists, 229 which is usually ignored by existing author identification 230 tasks [2], [46]. Suppose an academic system establishes a 231 profile for a researcher only if she/he has published at least 232 one paper, a lot of papers written by the new researchers 233 who publish papers for the first time, cannot be assigned to 234 any existing person in the system. Thus, the right person 235 should be either a real person or a non-existing person. In 236 summary, the problem is defined as: 237

**Problem 1 Disambiguation on the fly.** *Given a training set* 238  $\mathcal{D} = \{(\langle p, a \rangle, C)\}$ , for each target paper-author pair  $\langle p, a \rangle$  and 239 the corresponding candidate persons C, the right person  $c^*$  can 240 be either a real person in C denoted by  $c^+$  or a non-existing per-241 son denoted by NIL, and other persons except  $c^*$  in C are the 242 wrong persons denoted by  $\{c^-\}$ . The target is to learn a predic-243 tive function 244

$$\mathcal{F}: \{(\langle p, a \rangle, C)\} \to \{c^*\},\tag{2}$$

247

255

to assign a target paper-author pair to its right person.

In our problem, a is usually used to select candidate per- 248 sons and p is used to extract features to match the candi- 249 dates. To simplify the problem, we assume the historical 250 papers assigned to the candidates are correct. However, his- 251 torical errors cannot be avoided. Thus, we design an inde- 252 pendent model to check and correct the historical 253 assignments repeatedly. The study is left in the future. 254

# 3 CONNA

In this section, we first give an overview of the end-to-end 256 framework and then introduce the matching component 257 which is to match the most possible candidate to the target 258 pair and the decision component which is to decide whether 259 to assign the top matched candidate to the target pair or not 260 respectively. Finally, we introduce how to self-correct the 261 errors of the two components by jointly fine-tuning them 262 through reinforcement learning.

Fig. 3. The whole framework of training and predicting.

#### 264 **3.1 Overview**

265 At first, given a target pair  $\langle p, a \rangle$ , the candidate persons C are the persons having the relevant names with the target 266 author a. We define the relevant names as simple variants 267 of a's name, including moving the last name to the first and 268 keeping the initials of the names except for the last name. 269 For example, the variants of "Jing Zhang" include "Zhang 270 Jing", "J Zhang" and "Z Jing". For annotating a dataset for 271 training and evaluating the models of name disambigua-272 tion, this simple candidate generation strategy can already 273result in enough challenging candidates. 274

The whole process of name disambiguation is divided 275 into offline training and online predicting, which is shown 276 in Fig. 3. During the offline training process, we first train a 277 matching component to estimate the probability of match-278 ing each candidate to the target pair and make the matching 279 280 probability of the right person higher than those of the wrong persons for each target pair. The matching compo-281 282 nent constructs the training data from  $\mathcal{D} = \{(\langle p, a \rangle, C)\}$  as a 283 set of triplets  $\mathcal{D}^r = \{(\langle p, a \rangle, c^+, c^-)\}$ , where  $\langle p, a \rangle$  is the target paper-author pair,  $c^+$  is the real right person and  $c^-$  is a 284 wrong person from the candidates. The objective is to make 285  $\langle p, a \rangle$  closer to  $c^+$  than to  $c^-$ . Then, we train a decision com-286 ponent to accept each sample  $(\langle p, a \rangle, C) \in \mathcal{D}$  as the input 287 and output a label  $\hat{y}$  for the top matched person  $\hat{c} \in C$ , 288 where *C* is ranked by the trained matching component,  $\hat{y} =$ 289 1 indicates  $\hat{c}$  is the right person and  $\hat{y} = 0$  indicates  $\hat{c}$  is the 290 wrong person. We construct the training data  $D^c$  for the 291 decision component by extracting  $(\langle p, a \rangle, c^+)$  as the positive 292 instance (i.e., y = 1) and  $(\langle p, a \rangle, \hat{c}^{-})$  as the negative instance 293 (i.e., y = 0) from each sample ( $\langle p, a \rangle, C$ ), where  $\hat{c}^-$  indicates 294 the top matched wrong person in C. Finally, we fine-tune 295 the matching component based on the feedback (i.e., error 296 cases) of the decision component, and then fine-tune the 297 298 decision component based on the updated output of the matching component. Essentially, the matching component 299 tries to keep the relative distances between the right and the 300 wrong persons of each target pair, and the decision compo-301 302 nent devotes to optimize the absolute positions between the top matched persons of all the target pairs found by the 303 matching component. 304

During the online predicting process, to disambiguate a target pair  $\langle p, a \rangle$ , the matching component first finds out the top matched candidate person  $\hat{c}$ , then based on the similarity features  $\phi(\langle p, a \rangle, \hat{c})$  output by the matching component, 312

the decision component will predict the label  $\hat{y}$  for  $\hat{c}$  and 309 finally assign the person  $c^*$  to  $\langle p, a \rangle$ , where  $c^* = \hat{c}$  if  $\hat{y} = 1$  310 and  $c^* = \text{NIL}$  otherwise. 311

### 3.2 Matching

Basic Profile Model (BP). Let's imagine how humans assign a 313 paper to a person. The humans usually browse all the 314 papers published by the person to understand her/his affili- 315 ation, overall research interest, and frequently collaborated 316 authors, then comparing them with those of the paper. In 317 other words, humans directly compare the person's profile 318 with the target pair, which can guide us to build our model. 319 Thus, we name the model as the basic profile model. Specifi- 320 cally, we merge all the attributes of a paper and divide them 321 into a set of tokens to represent the paper, and then merge 322 the tokens of all the papers of a person into a unified set of 323 tokens to represent the person's profile. Based on the token- 324 based representations of the target paper and the person, 325 we can estimate the similarity between them. Note a com-326 plete author name or a word in titles, keywords, venues and 327 affiliations is viewed as a token. 328

Some metrics such as Jaccards Coefficient [30] and cosine 329 similarity [30] can easily capture the exact matches. However, 330 they suffer from the sparsity of the token-based representa- 331 tions. For example, the similarity is zero if two representations 332 do not contain any same tokens, even if they are semantically 333 similar. On the other hand, recently, some representation- 334 based models [12], [14] can successfully capture the soft/ 335 semantic similarities, as they embed the high-dimensional 336 sparse features into low-dimensional dense representations. 337 Through training on the labeled data, the model can reduce the 338 distance between the semantically similar inputs in the low- 339 dimensional space. However, these models may suffer from 340 the problem of semantic drift. For example, two token-based 341 representations with many overlapped tokens may become 342 dissimilar after being embedded by the model, as the global 343 representation may dilute the effect of the exact same tokens 344 by other different tokens. In summary, the above two types of 345 methods are good at either exact matching or soft matching. To 346 capture both the exact and soft matches, we adopt the interac- 347 tion-based models [5], [12], [43] widely used in information 348 retrieval. The interaction-based models first build a similarity 349 matrix between each candidate person and the target pair and 350 then apply an aggregation function to extract features from the 351 matrix. These models avoid learning the global representa-352 tions, thus can reduce the issue of semantic drift. 353

Similarity Matrix. We represent the matches between each 354 candidate and the target pair as a similarity matrix **S**, with 355 each element  $\mathbf{S}_{ij}$  standing for the basic interaction, i.e., the 356 cosine similarity  $\mathbf{S}_{ij} = \frac{\mathbf{P}_i \cdot \mathbf{c}_j}{||\mathbf{p}_i||\cdot||\mathbf{c}_i||}$  between  $\mathbf{p}_i$  and  $\mathbf{c}_j$ , where  $\mathbf{p}_i$  357 represents the embedding of the *i*th token in the target pair 358  $\langle p, a \rangle$  and  $\mathbf{c}_j$  represents the embedding of the *i*th token in 359 the candidate person *c*, which can be pre-trained by Word2-360 Vec [18], [23] or BERT [6].

*Aggregation Function.* For sentence matching, CNN [12], 362 [25] and RNN [39] are widely used as aggregation functions 363 to extract matching patterns from the similarity matrix. 364 However, different from sentence matching, title, keywords, 365 venue and affiliation are all short text. We need to pay more 366 attention to the occurrence of the exact same or semantically 367

Fig. 4. The basic profile model.

similar tokens. Thus we adopt an RBF kernel aggregation 368 function [43] to extract features. Specifically, the *i*th row  $S_i =$ 369 370  $\{S_{i0}, \ldots, S_{iM}\}$  of the similarity matrix — the similarities between the *i*th token of the target pair and each token of the 371 372 candidate person, is transformed into a feature vector  $\mathbf{K}(\mathbf{S}_i)$ , with each of the *k*th element  $K_k(\mathbf{S}_i)$  being converted by the 373 *k*th RBF kernel with mean  $\mu_k$  and variance  $\sigma_k$ . Then the fea-374 ture vectors of all the tokens in the target pair are summed 375 376 up into the final similarity embedding  $\phi(\langle p, a \rangle, c)$ , i.e.,

$$\phi(\langle p, a \rangle, c) = \sum_{i=1}^{N} \log \mathbf{K}(\mathbf{S}_i), \qquad (3)$$

378 379 381

382

$$\mathbf{K}(\mathbf{S}_i) = \{K_1(\mathbf{S}_i), \dots, K_K(\mathbf{S}_i)\},\tag{4}$$

**384** 385

$$K_{k}(\mathbf{S}_{i}) = \sum_{j=1}^{M} \exp\left[-\frac{(S_{ij} - \mu_{k})^{2}}{2\sigma_{k}^{2}}\right].$$
 (5)

The kernel with  $\mu = 1$  and  $\sigma \rightarrow 0$  only considers the exact matches between tokens, and others, e.g., with  $\mu = 0.5$ , counts the number of tokens in the candidate person whose similarities to a queried token in the target paper are close to 0.5. Thus, the kernel aggregation not only emphasizes the effect of exact matching but also captures the soft matches. Fig. 4 illustrates the model.

Multi-Field Profile Model (MFP). The basic profile model 393 does not distinguish different fields of attributes but groups 394 them together. However, it is not necessary to compare dif-395 ferent attributes, such as comparing authors with venues. 396 Moreover, it takes more effect to compare coauthor names 397 than other attributes. So we build a basic profile model on 398 399 each field of the attributes respectively, i.e., different attributes are not allowed to be compared, then aggregate the 400 401 similarity embeddings together by the corresponding attention coefficients estimated by 402

$$\alpha_f = \frac{\exp(w\phi(A_f^p, A_f^c) + b)}{\sum_f \exp(w\phi(A_f^p, A_f^c) + b)},$$
  
$$\phi(\langle p, a \rangle, c) = \sum_f \alpha_f \phi(A_f^p, A_f^c),$$
  
(6)

404

where  $\phi(A_f^p, A_f^c)$  denotes the similarity embedding between A<sup>p</sup><sub>f</sub> and  $A_f^c$  with  $A_f^p$  being the *f*th field of *p* and  $A_f^c$  being that of the candidate person *c*. Notations *w* and *b* denote the parameters. The model is named as multi-field profile model and is shown in Fig. 5.

Fig. 5. The multi-field profile model.

Multi-Field Multi-Instance Model (MFMI). A person usually 410 publishes multiple papers. Some persons even publish papers 411 of multiple topics on multiple fields of venues and collaborate 412 with multiple communities of persons. In this scenario, a target 413 paper can be only similar to a small part of a person's diverse 414 profile, but is totally irrelevant to other parts of the profile. 415 However, the multi-field profile model may dilute the similar- 416 ity with this small part when summing the similarities with all 417 the tokens in a person's profile together by Eq. (5). To reduce 418 the impact from the irrelevant papers, we build a multi-field 419 model between the target pair and each published paper of the 420 candidate person, and then aggregate the resultant similarity 421 embeddings of all the published papers by their correspond- 422 ing attention coefficients, which are estimated the same as 423 Eq. (6). The model is named as the multi-field multi-instance 424 model and is shown in Fig. 6. 425

*The Combination Model (CONNA<sup>r</sup>)*. Essentially, the multifield profile model captures the global similarities between 427 the target pair and a person's profile, while the multi-field 428 multi-instance model considers the local similarities 429 between the target pair and each of the papers published by 430 a person. Both of them can be explained intuitively, thus we 431 can combine their output similarity embeddings together as 432 the final feature embedding. We summarize different component variants in Table 1.

*Loss Function.* We use the triplet loss function to optimize 435 the matching component. Similar ideas has been also used 436 in [2], [46], [47]. Let  $D^r$  be a set of triplets with each triplet 437 denoted as  $(\langle p, a \rangle, c^+, c^-)$ , where  $c^+$  is the right person of the 438 target pair  $\langle p, a \rangle$  and  $c^-$  is a wrong person sampled from the 439 candidates, the triplet loss function  $\mathcal{L}(\Theta)$  is defined as 440

$$\begin{aligned} \mathcal{L}(\Theta) &= \sum_{(\langle p,a \rangle, c^+, c^-) \in \mathcal{D}^r} \mathcal{L}_{\Theta}(\langle p,a \rangle, c^+, c^-) \\ &= \sum_{(\langle p,a \rangle, c^+, c^-) \in \mathcal{D}^r} \max\{0, g(\phi(\langle p,a \rangle, c^-)) - g(\phi(\langle p,a \rangle, c^+)) + m)\}, \end{aligned}$$

$$(7) 442$$

Fig. 6. The multi-field multi-instance model.

TABLE 1 Matching Component Variants of CONNA

Component variants	Key idea
Basic Profile (BP)	The basic interaction-based model
Multi-field Profile (MFP)	Build BP for each field
Multi-field Multi-instance (MFMI)	Build MFP for each instance
CONNA <sup>7</sup>	Combine MFP and MFMI

where q is defined to be a non-linear function to transform 443 the similarity embedding  $\phi$  into a one-dimension matching 444 score that can be compared between the positive pair 445  $(\langle p, a \rangle, c^+)$  and the negative pair  $(\langle p, a \rangle, c^-)$ . Notation  $\Theta$  indi-446 cates the parameter of the matching component and m > 0447 is a margin enforcing a distance between positive pairs and 448 449 negative pairs. We optimize the triplet loss instead of directly optimizing the cross-entropy loss between the out-450 451 put matching score and the true label, as we aim at finding the top matched candidate from all the candidates for each 452 453 target pair, thus the objective should be keeping a relative order within the candidate persons of each target pair 454 instead of keeping a global order among all the (p, c) pairs. 455 The triplet loss is more direct and close to our objective than 456 the cross-entropy loss. 457

#### 458 **3.3 Decision**

482

459 The decision component is built upon the output of the 460 matching component to identify the right person, who can be either the top matched real person or NIL. The candidate per-461 sons C of each sample  $(\langle p, a \rangle, C) \in \mathcal{D}$  are ranked into C based 462 on the matching probabilities estimated by the matching 463 component. Note for the samples with  $c^* = c^+$ , the real right 464 person  $c^+$  may be ranked the first or not. Then the decision 465 component is trained to predict the first ranked person  $\hat{c} \in C$ 466 to be a right person (i.e.,  $\hat{y} = 1$ ) or a wrong person (i.e., 467  $\hat{y} = 0$ ). To achieve the goal, we construct the training data  $\mathcal{D}^c$ 468 from the ranked dataset  $\hat{\mathcal{D}} = \{(\langle p, a \rangle, C)\}$ . Specifically, from 469 each sample  $(\langle p, a \rangle, \hat{C})$ , we extract  $(\langle p, a \rangle, c^+)$  as the positive 470 instance (i.e., y = 1) and extract  $(\langle p, a \rangle, \hat{c}^{-})$  as the negative 471 instance (i.e., y = 0), where  $\hat{c}^-$  indicates the first ranked 472 wrong person in C. In another words, the positive instances 473 are only extracted from the samples with  $c^* = c^+$ , while the 474 475 negative instances are extracted from both the samples with  $c^* = c^+$  and the samples with  $c^* = \text{NIL}$ . For an instance 476  $(\langle p, a \rangle, c)$ , we use the similarity embedding  $\phi(\langle p, a \rangle, c)$  output 477 by the matching component as its feature. Thus,  $\mathcal{D}^c =$ 478  $\{(\phi(\langle p,a\rangle,c^+),y=1)\} \cup \{(\phi(\langle p,a\rangle,\hat{c}^-),y=0)\}.$ Then we 479 train a multi-layer perceptron  $h(\Phi)$ 480

$$h(\Phi): \{\phi(\langle p, a \rangle, c)\} \to \{y\},\tag{8}$$

483 where *y* is the label of the instance  $(\langle p, a \rangle, c)$ , whose value 484 equals 1 if  $(\langle p, a \rangle, c)$  is a positive instance and 0 otherwise.

#### 485 3.4 Reinforcement Self-Correction

We finally fine-tune the two components by jointly training them to correct their errors by themselves. The matching component can be viewed as the generator to generate the ranking list. Without the decision component, the triplet loss in Eq. (7) is used to measure whether the ranking list is good or not. However, as the final objective is to determine

whether the top ranked candidate is the right person or not, 492 the triplet loss is not enough to verify the effect. Fortunately, 493 we can use the prediction result of the top ranked candidate 494 by the decision component as the delayed feedback to the 495 ranking results of the matching component. Specifically, we 496 can punish the ranking list with the wrongly predicted top 497 candidate and reward the ranking list with the correctly pre- 498 dicted top candidate. Then based on the reward we update 499 the matching component, expecting the ranking lists gener- 500 ated by the matching component to the decision component 501 are more accurate. Followed by the motivation, we propose 502 fine-tuning the two components via reinforcement learning. 503 Specifically, the objective is to maximize the expected reward 504 of the ranking lists generated by the matching component 505

$$J(\Theta) = \sum_{(\langle p, a \rangle, \hat{C} \rangle) \in \hat{\mathcal{D}}} p_{\Theta}(\langle p, a \rangle, \hat{C}) R(y, \hat{y}), \tag{9}$$

where  $\hat{D}$  is the ranked training data,  $p_{\Theta}(\langle p, a \rangle, \hat{C})$  is the <sup>508</sup> probability of generating the ranking list  $\hat{C}$  of the target pair <sup>509</sup>  $\langle p, a \rangle$  by the matching component, and  $R(y, \hat{y})$  is the reward <sup>510</sup> function defined as follows: <sup>511</sup>

$$R(y,\hat{y}) = \begin{cases} 1 & \hat{y} = y; \\ 0 & \text{otherwise.} \end{cases}$$
(10)

where  $\hat{y}$  is the predicted label for the top-ranked candidate  $\hat{c}$  514 of  $\hat{C}$  and y is the ground truth label. The defined reward 515 function encourages the matching component to float the 516 right person at the top and push the wrong person away 517 from the top. The policy gradient algorithm [34] is adopted 518 to optimize the expected reward in Eq. (9), whose gradient 519 is calculated as 520

$$\nabla_{\Theta} J(\Theta) = \sum_{(\langle p, a \rangle, \hat{C}) \in \hat{\mathcal{D}}} R(y, \hat{y}) \nabla p_{\Theta}(\langle p, a \rangle, \hat{C}),$$

$$\simeq \sum_{(\langle p, a \rangle, \hat{c}, c^{-}) \in \mathcal{D}^{r}} R(y, \hat{y}) \nabla \mathcal{L}_{\Theta}(\langle p, a \rangle, \hat{c}, c^{-}).$$
(11)
522
523

Since the probability of a ranking list  $\hat{C}$  is not easy to be 524 estimated, we transform C into a set of triplets, with each 525 triplet including the target pair  $\langle p, a \rangle$ , the top ranked candi- 526 date  $\hat{c} \in C$  and a negative candidate  $c^- \in C$ . Then the loss of 527 a triplet in Eq. (7) is calculated and the losses of all the trip- 528 lets are summed up to approximately measure the ranking 529 performance of C. Thus, the gradient  $\nabla p_{\Theta}(\langle p, a \rangle, C)$  is 530 approximated by  $\nabla \mathcal{L}(\langle p, a \rangle, \hat{c}, c^{-})$  of all the triplets in C. 531 Then the parameters  $\Theta$  of the matching component can be 532 updated by the gradient. After the matching component is 533 tuned, the decision component is also updated based on the 534 updated similarity embeddings output by the matching 535 component. Algorithm 1 illustrates the joint training pro-536 cess, where we first pre-train the matching component and 537 the decision component, and then jointly fine-tune the two 538 components together. 539

# 4.1 Experimental Settings

We evaluate CONNA on two name disambiguation 543 datasets: 544

507

541

542

OAG-WhoIsWho<sup>3</sup>: Is the largest human-annotated name dis-545 ambiguation dataset so far, which is consist of 608,363 papers 546 belonging to 57,138 persons of 642 common names. Existing 547 work either leverage the disambiguating results by algorithms 548 in some well-known academic websites such as Scopus [28] 549 CiteSeerX [45], Web of Science [1] and PubMed [38], or anno-550 551 tate a much smaller datasets by human beings, such as 8,453 [9], 6,921 [15], 7,528 [35] and 2,946 annotated persons [24]. 552 Compared to the most popular KDD Cup 2013 challenge data-553 set, the OAG-WhoIsWho is also superior to it both in quantity 554 (608,363 versus 424,384 in terms of the number of papers) and 555 quality (fully human-labeled versus partially human-labeled). 556 We annotate the dataset as follows. From the AMiner system, 557 we choose 642 highly ambiguous names, create the relevant 558 names by the candidate generation strategy in Section 3.1 and 559 560 select all the authors for each name, collect all the papers assigned for each author and extract title, authors, organiza-561 562 tions, keywords and abstract for each paper. We also collect all the unassigned papers for each name from AMiner. Since the 563 564 assigned papers may be wrongly assigned and the papers are not fully assigned, additional efforts are needed to clean and 565 reassign the papers. First, we clean the dataset by removing 566 the wrongly assigned papers or splitting the papers of an 567 author into different clusters. Second, we annotate the unas-568 signed papers or merge the papers of two authors. We aim to 569 clean the dataset as much as possible but increase the highly 570 reliable assignments. According to the purpose, we only hire 571 one annotator to perform the cleaning step, but hire three anno-572 tators to perform the assignment step respectively and then 573 obtain the final results by majority voting their annotations. 574 575 Besides, an annotation tool is developed to recommend highly reliable removing, splitting, assigning or merging operations to 576 577 the annotators to simplify the human annotation process.<sup>4</sup>

KDD Cup [29]. Is the dataset used in the KDD Cup 2013 578 579 challenge 1 to address name disambiguation problem. We collect the training data containing 3,739 authors and 580 123,447 papers, as only the training labels are published. 581 We only use title, organizations, keywords and abstract as 582 features, but ignore coauthor names. As shown in Fig. 7a, 583 the distribution of same-coauthor ratio is extremely skewed. 584 According to Eq. (1), same-coauthor ratio equalling 1 means 585 the second similar candidate and the least similar candidate 586 have the same number of same-coauthors with the target 587 588 pair. In another word, the most similar candidate is significantly different from all the other candidates when only 589 590 considering the coauthor name features. Thus, 98 percent target pairs holding 1.0 same-coauthor ratio means only 591 using the coauthor names can correctly assign 98 percent 592 target pairs. In fact, when considering the coauthor name 593 feature, any baselines including our model can easily 594 595 achieve approximate 99 percent HR@1. Thus, for increasing the difficulty, we ignore coauthor names on this dataset. 596

#### 4.1.2 Comparison Methods 597

Matching Component. To evaluate the matching perfor-598 mance, we compare feature engineering-based GBDT and 599 three embedding-based models: 600

7

Fig. 7. (a) Distribution of the same-coauthor ratio on KDD Cup dataset; (b) The effects of different attributes.

GBDT. Is a widely used model to solve KDD Cup 2013 601 challenge-1 [7], [19], [48]. We train a GBDT model to esti- 602 mate a matching probability between each candidate and 603 the target pair. The extracted features for GBDT are 604 shown in Table 2. As the model can directly predict a 605 label for each candidate, it also be used for deciding to 606 assign the most matched candidate to the target pair if its 607 label is 1. 608

Algorithm 1. Reinforcement Joint Training					
<b>Input</b> : A training set $\mathcal{D} = \{(\langle p, a \rangle, C)\}.$					
Output: A matching component and a decision component					
parametrized by $\hat{\Theta}$ and $\Phi$ respectively.	612				
1: Build $\mathcal{D}^r = \{(\langle p, a \rangle, c^+, c^-)\}$ from $\mathcal{D}$ ;	613				
2: Pre-train $\Theta$ of the matching component on $\mathcal{D}^r$ ;	614				
3: Rank $\mathcal{D}$ by the matching component to generate $\hat{\mathcal{D}}$ ;	615				
4: Build $\mathcal{D}^c = \{(\phi(\langle p, a \rangle, c), y)\}$ from $\hat{\mathcal{D}}$ ;	616				
5: Pre-train $\Phi$ of the decision component on $\mathcal{D}^c$ ;	617				
6: repeat	618				
7: for $(\langle p, a \rangle, \hat{C}) \in \hat{\mathcal{D}}$ do	619				
8: Predict $\hat{y}$ for $\hat{c}$ by the decision component;	620				
9: Calculate $R(y, \hat{y})$ by Eq. (10);	621				
10: Calculate $\nabla_{\Theta} J(\Theta)$ by Eq. (11);	622				
11: $\Theta \to \Theta + \mu \nabla_{\Theta} J(\Theta)$ , where $\mu$ is the learning rate;	623				
12: Re-rank $\mathcal{D}$ to generate $\hat{\mathcal{D}}$ by the matching component;	624				
13: Re-generate $\hat{\mathcal{D}}^c$ from $\hat{\mathcal{D}}$ ;	625				
14: Update $\Phi$ of the decision component on $\mathcal{D}^c$ ;	626				
15: until Convergence	627				

Camel [46]. Is a representation-based model. Given a trip- 628 let  $(\langle p, a \rangle, c^+, c^-)$ , it first represents  $\langle p, a \rangle$  by p's title, and rep- 629 resents  $c^+$  and  $c^-$  by their identities. Then it calculates the 630 matching scores for both  $(\langle p, a \rangle, c^+)$  and  $(\langle p, a \rangle, c^-)$ , and 631 finally optimizes the difference between their matching 632 scores. 633

*HetNetE* [2]. Is similar as Camel except that  $\langle p, a \rangle$  is repre-634 sented by all its attributes. 635

GML [47]. Is a representation-based model to identify 636 whether two papers are written by the same person through 637 optimizing a triplet loss. The model accepts the pre-trained 638 embeddings of all the tokens in a paper as input and output 639 an embedding for the paper. We represent a person by aver-640 aging all his/her papers' embeddings. 641

Decision Component. To evaluate the performance of the 642 decision component, we compare two strategies: 643

Threshold [8]. Picks the top matched person whose score 644 is lower than a threshold as NIL, where the threshold is 645 determined as the value when the best accuracy is obtained 646 on a validation set. We use the same matching model as our 647 proposed method to obtain the top matched persons. 648

TABLE 2 Features Extracted for GBDT Model

No.	Feature description
1	The number of the papers of $c$
2	The number of the coauthors of $a$ in $p$
3	The number of the coauthors of $c$
4	The number of the same coauthors between $a$ and $c$
5	Ratio of the same coauthors between $a$ and $c$ in $p$ 's coauthor names
6	Ratio of the same coauthors between $a$ and $c$ in $c$ 's coauthor names
7	Frequency of $a$ 's affiliation in $c$ 's affiliations
8	Ratio of $a$ 's affiliation in $c$ 's affiliations
9	Cosine similarity between <i>a</i> 's affiliation and <i>c</i> 's affiliations
10	Jaccards similarity between $a$ 's affiliation and $c$ 's affiliations
11	Distinct number of venues of <i>c</i>
12	Frequency of $p$ 's venue in $c$
13	Ratio of $p$ 's venue in $c$
14	Cosine similarity between $p$ 's venue and $c$ 's venues
15	Jaccards similarity between $p$ 's venue and $c$ 's venues
16	Cosine similarity between $p$ 's title and $c$ 's titles
17	Jaccards similarity between $p$ 's title and $c$ 's titles
18	Distinct number of keywords in $c$
19	Frequency of $p$ 's keywords of $c$
20	Ratio of $p$ 's keywords in $c$
21	Cosine similarity between $p$ 's keywords and $c$ 's keywords
22	Jaccards similarity between $p$ 's keywords and $c$ 's keywords

*p*: target paper, *a*: target author in *p*, *c*: candidate person.

649 Heuristic Loss [4]. Unifies the NIL decision and the matching process by incorporating the costs of assigning a paper 650 to a wrong NIL person or assigning an unlinkable paper to 651 a wrong existing person into the loss function of ranking 652 the wrong person before the right person. NIL is inserted as 653 an additional candidate person for each paper. The repre-654 sentations of p and c which are made in the same way as 655 656 GML, are concatenated as the input of a neural network to produce their matching score. When c = NIL, the represen-657 658 tation of *c* is not included.

659 Variants of Our Model. We also compare different variants 660 where CONNA<sup>*r*</sup>(BP), CONNA<sup>*r*</sup>(MFP), CONNA<sup>*r*</sup>(MFMI) and CONNA<sup>*r*</sup> correspond to the variants in Table 1. CrossEntropy 661 modifies CONNA<sup>r</sup> by replacing the triplet loss with the cross-662 entropy loss, which can be directly used for deciding the 663 assignments. CONNA trains CONNA<sup>r</sup> plus a decision 664 component once. CONNA+Fine-tune jointly trains the two 665 components in CONNA. 666

#### 667 4.1.3 Evaluation Settings

For each dataset, we randomly sample 20 percent persons 668 for testing and divide the rest into training, which results in 669 45,711 authors for training and 11,427 authors for testing on 670 OAG-WhoIsWho dataset, and 2,991 authors for training 671 and 748 authors for testing on KDD Cup dataset. For each 672 author in both training and testing data, we first sort their 673 674 papers by the published year in ascending order. Then we choose the latest 20 percent papers as the author's unas-675 signed paper and leave 80 percent papers as the author 676 profile. 677

We first evaluate the matching of the candidate persons to the target pair, and further evaluate the decision of the top matched person as the right person or NIL.

Matching Evaluation. For evaluating the matching performance, we sample 10,000 target pairs from the training data. Each target pair paired with its right person composes a positive instance. We also sample 9 wrong persons paired with each target paper to compose 9 negative 685 instances. The process results in 90,000 triplets for training. 686 For testing, we sample 2,000 target pairs from the test data, 687 where each one is associated with the right person and 19 688 wrong persons. 689

The wrong persons are sampled from the candidates. We 690 follow the name variant strategy in Section 3.1 to generate 691 candidates on OAG-WhoIsWho. While for KDD Cup, 692 names are so different that no candidates can be found by 693 simply varying names. Instead, we calculate the Jaro-Win- 694 kler similarity between a candidate's name and the target 695 author, and select the candidates whose scores are larger 696 than 0.5 as the wrong persons. 697

We use Hit Ratio at top k (HR@k) and mean reciprocal 698 rank (MRR) as the metrics for evaluating whether the right 699 person will be ranked at the top among all the candidates. 700 Since there is only one right person for each target pair, 701 HR@k measures the percentage of the candidate lists with 702 the right person ranked before top k. MRR measures the 703 average of reciprocal ranks of the right persons. Higher 704 HR@k and MRR indicate better performance. 705

Decision Evaluation. We construct the training data for the 706 decision component upon the output of the matching com- 707 ponent. Specifically, we also use the 10,000 positive instan-708 ces for the matching component as those for the decision 709 component. Then we extract the target pairs and the corre-710 sponding top matched wrong persons to compose the nega-711 tive instances. For testing, in addition to the 2,000 target 712 pairs and the corresponding candidates including the right 713 persons (i.e., positive sample  $(\langle p, a \rangle, C)$  with  $c^* = c^+$ ), we 714 extract extra 2,000 target pairs and the corresponding candi-715 dates excluding the right persons (i.e., negative sample 716  $(\langle p, a \rangle, C)$  with  $c^* = \text{NIL}$ . Conveniently, we remove the 717 right person  $c^+$  from each positive sample and create a neg- 718 ative sample by the remaining wrong persons. We count the 719 number of true positive (tp), false negative (fn), true nega-720 tive (tn) and false positive (fp) samples and then calculate 721 precision, recall and f1 722

$$tp = |\{c^* = c^+ \text{ and } \hat{c} = c^+ \text{ and } \hat{y} = 1\}|,$$
  

$$fn = |\{c^* = c^+ \text{ and } \hat{y} = 0\}|,$$
  

$$tn = |\{c^* = \text{NIL and } \hat{y} = 0\}|,$$
  

$$fp = |\{c^* = \text{NIL and } \hat{y} = 1\}\cup$$
  

$$\{c^* = c^+ \text{ and } \hat{c} \neq c^+ \text{ and } \hat{y} = 1\}|,$$
  
(12)

724

where tp is the number of the positive samples, with the 725 right persons ranked at the first (i.e.,  $\hat{c} = c^+$ ) and also pre-726 dicted as the right persons (i.e.,  $\hat{y} = 1$ ). On the contrary, fn 727 counts the positive samples with  $\hat{y} = 0$ . Notation tn denotes 728 the number of negative samples with the first ranked per-729 sons predicted as the wrong persons (i.e.,  $\hat{y} = 0$ ), while fp 730 counts the negative samples with  $\hat{y} = 1$  and also counts the 731 positive samples with the wrong persons ranked at the first 732 (i.e.,  $\hat{c} \neq c^+$ ) but still predicted as the right persons (i.e., 733  $\hat{y} = 1$ ). Since we aim at assigning the target pair to an exist-734 ing right person and also assigning it to NIL if there is no 735 right person, we calculate precision and recall for both the 736 cases with  $c^* = c^+$  and  $c^* = \text{NIL}$ 

$$c^* = c^+ : \operatorname{Pre.} = \frac{\operatorname{tp}}{\operatorname{tp} + \operatorname{fp}}, \quad \operatorname{Rec.} = \frac{\operatorname{tp}}{\operatorname{tp} + \operatorname{fn}};$$
  
$$c^* = \operatorname{NIL} : \operatorname{Pre.} = \frac{\operatorname{tn}}{\operatorname{tn} + \operatorname{fn}}, \quad \operatorname{Rec.} = \frac{\operatorname{tn}}{\operatorname{tn} + \operatorname{fp}}.$$
 (13)

**739** 740

#### 741 4.1.4 Implementation Details

We divide the attributes of a paper into two fields: coauthor 742 names and other attributes including title, abstract, organi-743 zations and keywords, as coauthor names have no literal or 744 semantic overlaps with other attributes. We pre-train an 745 embedding for each author name and each word. Specifi-746 cally, we use Word2Vec to train an embedding for an author 747 name in the context of all the coauthors' names in a paper, 748 and train an embedding for a word in the context of all the 749 other occurred words in title, keywords, venue and affilia-750 tion. We set the dimension of the embedding as 100. To 751 752 enable matrix operation, for each paper or candidate person, we restrict the maximal number of author names to 753 754 100, the maximal number of words to 500, and the maximal number of papers published by each person to 100. 755

Function *g* in Eq. (7) is instantiated as a 3-layer MLP followed by a ReLU function which transforms a similarity embedding  $\phi(\langle p, a \rangle, c)$  into a 1-dimensional score. Function *h* in Eq. (8) is also a 3-layer MLP which transforms a  $\phi(\langle p, a \rangle, c)$  into 2-dimensional classification probabilities.

#### 765 4.2 Performance Analysis

### 766 4.2.1 Matching Performance

Overall Matching Performance. Table 3 shows the matching performance of the proposed model, the model variants and the comparison methods on the two datasets OAGWhoIsWho and KDD Cup. In terms of HR@1, the proposed CONNA+Fine-tune achieves 3.80 to 49.90 percent improvement over all the baseline methods.

Camel, HetNetE and GML are all representation-based 773 deep learning models, which can capture the soft/semantic 774 matches, but they will dilute the effect of the exact matches of 775 tokens due to the global representations of the papers and per-776 sons. Among the three models, HetNetE uses all the attributes 777 of a paper rather than the single title to represent a paper, 778 which achieves better performance than Camel. Camel and 779 HetNetE represent the candidate persons only based on their 780 identities. Thus they suffer from the sparsity issue, i.e, the 781 782 embeddings of the persons cannot be trained accurately if they publish few papers. GML avoids the sparsity issue 783 through representing persons by their published papers. 784 However, it is difficult to directly compare the embeddings of 785 a long text (i.e, all the papers of a candidate person) and a 786 short text (i.e., a target paper). 787

In the name disambiguation problem, the exact matches between tokens especially the matches between coauthor names are more important than the soft matches, thus although GBDT only captures the exact matches, it performs better than the representation-based models. The proposed interaction-

TABLE 3 Performance of the Matching Results (%)

GML	70.87	94.53	82.59	72.13	95.34	82.90	
GBDT	87.30	98.10	92.71	84.18	92.09	89.59	
CONNA <sup>r</sup> (BP)	86.20	96.40	92.20	91.12	95.72	93.73	
CONNA <sup>r</sup> (MFP)	88.00	98.75	93.25	-	-	-	
CONNA <sup>r</sup> (MFMI)	89.45	98.40	93.82	91.45	95.80	94.03	
CONNA	90.45	98.30	94.46	92.10	96.35	94.66	
CONNA+Fine-tune	<b>91.10</b>	<b>98.45</b>	<b>94.86</b>	<b>92.60</b>	<b>96.71</b>	<b>94.95</b>	

based matching component in CONNA captures both the exact and the soft matches through comparing local representations of each token pairs instead of comparing the global representations of papers and persons. Specifically, the kernel aggregation function used in the matching component summarizes a frequency distribution of the exact matches and different kinds of soft matches, which can't dilute the effect of extract matches by the other soft matches. Thus, the proposed matching component performs better than all the comparison methods.

Compared with CONNA, the performance of CONNA 802 +Fine-tune is further improved, as the decision component 803 gives additional feedbacks to supervise the ranking of the 804 matching component. The result indicates that through 805 jointly fine-tuning of the two components, the errors of the 806 matching component can be reduced. 807

Comparing the results on the two datasets, we can see that 808 the advantage of our model over the feature engineering- 809 based GBDT is much more significant on KDD Cup (+8.42% 810 in HR@1) than OAG-WhoIsWho (+3.80% in HR@1). Since 811 coauthor features are not used on the KDD Cup, the results 812 indicate that CONNA can better capture the semantics of the 813 attributes except coauthor names. 814

*Multi-Field Effect*. We conduct an ablation study to analyze 815 the effects of different modeling strategies on the matching 816 component. Since only one field is used on the KDD Cup 817 dataset, we analyze the effect of multi-fields on the OAG- 818 WhoisWho dataset. From Table 3, we can see that CONNA<sup>*r*</sup> 819 (MFP) performs better than CONNA<sup>*r*</sup>(BP) (improving 1.8 820 percent in terms of HR@1), which indicates that it is necessary to build the interaction-based models for different 822 attributes separately and distinguish their effects. 823

We also investigate the effects of different fields by removing coauthor names and other attributes respectively based 825 on the model CONNA. The experimental results in Fig. 7b 826 show that removing either coauthor names or other attributes 827 performs significantly worse (-5.80%-7.05%, HR@1) than 828 CONNA, which indicates that both coauthor names and other 829 attributes impact the performance obviously. What's more, 830 removing names is comparable to removing other attributes, 831 which indicates that coauthor names are more important than 832 all the other attributes on the task of name disambiguation. 833

*Multi-Instance Effect.* Table 3 also shows that on OAG- 834 WhoisWho, CONNA<sup>*r*</sup>(MFMI) performs better than CON- 835 NA<sup>*r*</sup>(MFP) (+1.45% in terms of HR@1), which demonstrates 836 the strength of distinguishing different papers of a person. 837 HR@1 of CONNA<sup>*r*</sup>(MFMI) is further improved by 1.00 per- 838 cent if we combine the profile model CONNA<sup>*r*</sup>(MFP) and 839

Fig. 8. Case study of multi-field effect.

the multi-instance model CONNA<sup>r</sup> (MFMI) as CONNA. The
result indicates that both the global similarity between the
target paper and a candidate's whole profile, and the local
similarities between the target paper and each paper of a
candidate take effects on matching performance. The results
on KDD Cup also present the advantages of multi-instances.

846 Interpretability of the Matching Component. We present some cases in Figs. 8 and 9 to demonstrate the interpretabil-847 848 ity of the proposed matching component. From Fig. 8, we can see that although the number of the matched tokens 849 between the target paper and the positive candidate person 850 is less than that of the negative candidate person, the 851 matched coauthors are more important than the matched 852 words in titles and venues, because the attention  $\alpha$  learned 853 by our model for the matched coauthors on the positive can-854 didate is 0.69, comparing with 0.31 learned for the matched 855 titles and venues. And the attention learned on the negative 856 candidate also emphasizes the matched coauthors. CONNA 857 distinguishes different fields' effects by the attention, thus it 858 859 can correctly identify the positive candidate, while the basic profile model CONNA<sup>*r*</sup>(BP) wrongly returns the negative 860 861 candidate as the most matched candidate, as it treats the matches in all the fields equally. 862

In Fig. 9, we present the affiliation of "Dan Chen" in both 863 the target paper and the positive candidate. It is shown that a 864 paper of the positive candidate has the same affiliation with 865 the target paper, and the corresponding attention  $\beta$  learned 866 by our model for the paper is 0.79, while the values of  $\beta$ 867 learned for other papers are much smaller than this paper. 868 CONNA distinguishes different papers' effects, thus it can 869 870 correctly identify the positive candidate, while the basic profile model CONNA<sup>*r*</sup>(BP) treats the matches in all the papers 871 872 equally, which dilutes the effects of similar papers by the other irrelevant papers. The learned attentions for different 873 fields and different papers both demonstrates the interpret-874 ability of the proposed matching component. 875

Fig. 9. Case study of multi-instance effect.

Matching Performance on Different Scenarios. We conduct 876 additional experiments on the matching performance of dif- 877 ferent baselines and CONNA with different same-coauthor 878 ratios on OAG-WhoIsWho dataset and present the results in 879 Fig. 2. We can see that HR@1 of the embedding-based mod- 880 els, i.e., Camel, HetNetE, GML and CONNA drop more 881 slightly (drops from 6.63 to 18.73 percent) than feature-engi-882 neering based GBDT (drops more than 29.69 percent) when 883 the same-coauthor ratio decreases from 1.0 to 0.1. This indi-884 cates that the embedding-based model can better capture the 885 semantic matches when the coauthor features are week. 886 Especially when the same-coauthor ratio is less than 0.1, the 887 performance gap between CONNA and GBDT is signifi-888 cantly more than 16 percent. The result indicates that 889 CONNA is more suitable to tackle the hard cases, i.e. the 890 cases that are hardly predicted by similar coauthors. 891

### 4.2.2 Decision Performance

Table 4 shows the final decision performance of the pro- 893 posed model and the comparison methods. Comparing 894 with other methods, in terms of F1, the proposed joint 895 model CONNA+Fine-tune achieves 1.69-19.84 percent 896 improvement on the samples with  $c^* = c^+$  and 1.21-14.03 897 percent improvement on the samples with  $c^* = \text{NIL}$ . We 898 evaluate the results on both of the samples as we aim at not 899 only assigning the target papers to the right persons if they 900 exist, but also assigning them to NIL if the right persons do 901 not exist. The problem in this paper is not merely a match-902 ing or a classification decision problem, but can be solved 903 by first matching each candidate to the target paper p and 904 then deciding whether the top matched person is right or 905 not. Thus, we need to not only keep the relevant order 906 within each candidate list, but also globally distinguish all 907 the positive pairs from all the negative pairs. 908

892

GBDT and CrossEntropy only aim to optimize the global 909 positions of all the  $(\langle p, a \rangle, c)$  pairs, but ignore the relative 910 order within each candidate list. Although the globally pre-911 dicted probabilities can be used to compare the candidates 912

TABLE 4 Performance of the Decision Results (%)

Model	OAG-WhoIsWho					KDD Cup						
	Samples with $c^* = c^+$			Samples with $c^* = NIL$		Samples with $c^* = c^+$			Samples with $c^* = \text{NIL}$			
	Pre.	Rec.	F1	Pre.	Rec.	F1	Pre.	Rec.	F1	Pre.	Rec.	F1
GBDT	82.87	72.40	77.28	75.39	85.04	79.98	83.64	71.64	77.17	75.20	85.98	80.23
Threshold	79.33	57.60	66.38	66.47	84.07	74.24	74.89	71.00	72.90	72.43	76.20	74.27
Heuristic Loss	71.79	78.40	74.95	76.21	69.20	72.54	85.14	69.60	76.59	74.29	87.85	80.50
CrossEntropy	79.42	82.33	80.85	81.66	78.67	80.14	89.60	82.79	86.06	86.15	88.05	87.09
CONNA	79.53	89.87	84.38	88.35	76.87	82.21	88.44	86.20	87.31	86.54	88.73	87.62
CONNA+Fine-tune	82.47	90.33	86.22	89.31	80.80	84.84	89.87	85.73	87.75	86.36	90.33	88.30

Fig. 10. Convergence analysis.

of each target paper, the relative order is not directly opti-913 mized, leading to a lot of mistakes in the final results. 914 Threshold can be viewed as a global optimization model, 915 but merely uses a heuristic threshold to distinguish differ-916 917 ent complicated cases. Heuristic Loss incorporates the costs related to NIL into the original loss of ranking the wrong 918 919 persons before the right persons, but it suffers from the heuristically configured weights of different costs. 920

CONNA first estimates the matching probability of each 921 candidate to the target pair and then decides the top 922 923 matched candidate. This two-step strategy which is widely adopted in entity linking [22], [27] is proved to be effective. 924 Compared with CONNA, the performance of CONNA 925 +Fine-tune is further improved, as some of the wrongly-pre-926 dicted instances are gradually represented better to gener-927 ate accurate similarity embeddings by the iteratively 928 refined matching component, which will finally increase the 929 number of rightly predicted instances. The result demon-930 strates that the errors of the decision component can be 931 932 reduced through jointly fine-tuning of the two components.

Convergence Analysis. We plot the train/test loss of the
 matching component and the decision component with the
 increase of the joint training epochs. The results in Fig. 10
 show that the performance of the two components both
 decrease sharply at the beginning of the joint training and
 then gradually change stable, which indicate the conver gence of CONNA+Fine-tune.

#### 940 4.3 Online Deployment on AMiner

Table 5 presents the average time cost of assigning each target 941 paper by the proposed CONNA model and the best baseline 942 GBDT. We implement the experiments by Tensorflow and 943 run the code on an Enterprise Linux Server with 40 Intel(R) 944 Xeon(R) CPU cores (E5-2640 v4 @ 2.40 GHz and 252G mem-945 ory) and 1 NVIDIA Tesla V100 GPU core (32G memory). Since 946 GBDT is a classification model without the matching compo-947 nent, we only present the cost of the decision process, which 948 uses the label of the top predicted candidate as the predictive 949 950 result. From Table 5, we can see that CONNA is about  $1.83 \times$ slower than GBDT, which is mainly determined by the feature 951 preparing process. Although CONNA performs much better 952 than GBDT on both the ranking and the decision performance, 953 from Fig. 2, we can see for about 62.17 percent easy samples, 954 i.e., the target pairs with the same-coauthor ratio larger than 955 0.9, the ranking performance of GBDT is comparable to 956 CONNA, where the ranking performance directly determines 957 the final decision performance of the top-1 candidates. Thus, 958 to improve the online assignment efficiency meanwhile keep-959 ing the assignment performance, for each target pair, if its 960

TABLE 5 Average Time Cost(ms) of Assigning Each Target Pair

Model	Feature Preparing	Matching	Decision
GBDT	183.34	-	3.61
CONNA	260.45	76.12	6.34

same-coauthor ratio is larger than 0.9, we directly apply 961 GBDT to perform paper assignment, otherwise we apply 962 CONNA to complete the task. 963

In addition, the online candidate selection is a little different from the offline name variant strategy explained 965 in Section 3.1. To improve the recall of the online predicting 966 as much as possible, we adopt ElasticSearch<sup>5</sup> to perform 967 fuzzy search for similar candidates with each target author. 968 Compared with this online fuzzy strategy, the offline candi-969 date selection is more strict, as for annotating high-quality 970 name disambiguation dataset, the simple name variant 971 strategy can already produce enough challenging candi-972 dates. However, the fuzzy strategy may result in too many 973 noisy candidates, which increase annotation efforts. 974

We develop a demo of disambiguation on the fly in AMi- 975 ner,6 and show two screenshots of the demo in Fig. 11. In 976 the demo, users are allowed to search a paper by its title, 977 then select the expected paper and click one author name to 978 see the disambiguation results of the paper with the current 979 name. Under the selected paper, we present the most 980 matched candidates by the trained matching component in 981 CONNA on the left, and show the decision result of the 982 assigned person by the trained decision component in 983 CONNA on the right. Fig. 11a shows a case with  $c^* = c^+$ . 984 We can see that our model can correctly match "Jing Zhang" 985 from Renmin University for the author "Jing Zhang" in the 986 paper "StructInf: Mining Structural Influence from Social 987 Streams" at the top and then decide the top matched one as 988 the final assigned person. Fig. 11b shows a case with  $c^* = 989$ NIL. Since "Bo Chen" of the paper "MEgo2Vec: Embedding 990 Matched Ego Networks for User Alignment Across Social 991 Networks" is a postgraduate student whose profile has not 992 been established by AMiner, none of the existing "Bo Chen" 993 should be assigned to the paper. Our model correctly 994 assigns NIL to this case. Besides, since errors are still inevi- 995 table, we allow the users to provide feedback to our decision 996 results. Specifically, users are allowed to directly "submit" 997 the result if they agree with it, otherwise, they can choose 998 another right person from the top matched persons. The 999 feedback can be simply regarded as new training instances 1000 to update the decision performance at each step of the joint 1001 training. 1002

## 5 RELATED WORK

This paper is related to the problems of name disambigua- 1004 tion from scratch, author identification and entity linking. 1005

*Name Disambiguation From Scratch.* Much effort has been 1006 made to disambiguate names from scratch defined as: given 1007 a set of papers written by the authors with similar name, it 1008 targets at partitioning all the papers into several disjoint 1009

<sup>5.</sup> https://www.elastic.co

<sup>6.</sup> http://na-demo.aminer.cn/

(b) A  $c^{2}$  = NIL case.

Fig. 11. A demo of disambiguation on the fly in AMiner.

clusters, with each of them corresponds to a real person. 1010 Existing work first represent papers by traditional feature 1011 engineering methods [3], [13], [35], [40], [42] or embedding 1012 models [26], [41], [45], [47] and then adopt a clustering 1013 algorithm such as hierarchical agglomerative clustering [3], 1014 [26], [41], [45], [47], K-means [40], [49], DBSCAN [13] or 1015 semi-supervised clustering [21] to partition these papers. 1016 Embedding models further include graph auto-encoder [47], 1017 heterogeneous GCN [26] and adversarial representation 1018 learning [41]. Continuous name disambiguation is formal-1019 1020 ized differently from the above problem, thus it can not be solved by the above methods. 1021

Author Identification. Several works devote to anonymous 1022 author identification for a paper, which assume the authors 1023 of the target paper are unknown in a double-blind setting. 1024 For example, Chen et al. [2] and Zhang et al. [46] both opti-1025 mize the difference between the right and the wrong 1026 authors. However, their models cannot be applied to unseen 1027 authors in the training set, as they only consider the identi-1028 ties of the authors. While we model authors' profiles, which 1029 do not depend on authors' identities. KDD Cup 2013 held 1030

an author identification challenge to solve the similar prob- 1031 lem. However, the situation that no right person exists was 1032 not considered and all the participations devoted to feature- 1033 engineering methods [7], [48]. 1034

Entity Linking. Entity linking aims at linking the mentions 1035 extracted from the unstructured text to the right entities in a 1036 knowledge graph [31]. Feature-based [17] or neural models 1037 such as skip-gram [44], autoencoder [11], CNN [33], 1038 LSTM [16] are proposed to calculate the similarity between 1039 the context of a mention and a candidate entity. The NIL 1040 problem is widely studied in entity linking. The main solu- 1041 tions usually include the NIL threshold methods [8], [32] 1042 predicting the mention as unlinkable if the score of the top 1043 ranked entity is smaller than a NIL threshold, the classifica- 1044 tion methods [22], [27] which predict the unlinkable men- 1045 tions by a binary classifier, and the unified models 1046 incorporating unlinkable mention prediction process into 1047 entity matching process [4], [10]. Different from above, we 1048 jointly train the NIL decision model and the candidate 1049 matching model to boost both of their performance. 1050

# 6 CONCLUSION

This paper presents the first attempt to formalize and solve 1052 the problem of name disambiguation on the fly by consider- 1053 ing different cases of assignments, in particular when a 1054 paper cannot be assigned to any existing persons in the sys- 1055 tem. We propose a novel joint model that consists of a match- 1056 ing component and a decision component, where a multi- 1057 field multi-instance interaction-based model is trained to 1058 match the candidates to each target paper, and then a classifi- 1059 cation decision model is trained to decide whether to assign 1060 the top matched candidate to the target paper or not. 1061 Through reinforcement joint fine-tuning, the two compo- 1062 nents can bootstrap each other and self-correct some of their 1063 errors. The experimental results on the recent largest dataset 1064 for name disambiguation demonstrate that the proposed 1065 model performs significantly better than state-of-the-art 1066 baseline methods. The model has already been deployed on 1067 AMiner to disambiguate the online papers. 1068

Bo Chen is currently working toward the post- 1233 graduate degree in the Information School, 1234 Renmin University of China, Beijing, China. His 1235 research interests include data integration and 1236 knowledge graph mining and he recently focuses 1237 on entity disambiguation in academic networks. 1238

#### IEEE TRANSACTIONS ON KNOWLEDGE AND DATA ENGINEERING

1256

1257

Jing Zhang received the master's and PhD degrees from the Department of Computer Science and Technology, Tsinghua University, Beijing, China. She is an assistant professor with the Information School, Renmin University of China. Her research interests include knowledge graph constructing and mining.

Jie Tang (Senior Member, IEEE) is a professor in the Department of Computer Science and Technology, Tsinghua University. His research interests include data mining, social network, and machine learning. He was honored with the SIGKDD Testof-Time Award in Applied Data Science.

Lingfan Cai is currently working toward the postgraduate degree in the Information School, Renmin University of China, Beijing, China. His research interests include name disambiguation in academic networks.

Shu Zhao received the PhD degree from Anhui 1263 University, Hefei, China, in 2007. She is a professor 1264 with the School of Computer Science and Technol- 1265 ogy, Anhui University. Her current research inter- 1266 ests include social network, machine learning, and 1267 granular computing. 1268

Hong Chen received the PhD degree from the 1269 Institute of Computing Technology, CAS, Beijing, 1270 China. She is a professor of the Renmin Univer- 1271 sity of China. Her research interests include data 1272 privacy, big data management, and data analysis 1273 based on new hardwares. She is a distinguished 1274 member of the CCF. 1275

Cuiping Li received the PhD degree from the 1276 Institute of Computing Technology, CAS, Beijing, 1277 China. She is currently a professor at the Renmin 1278 University of China. Her current research inter- 1279 ests include database systems, social network 1280 analysis, and data mining. 1281

Zhaoyu Wang is currently working toward the postgraduate degree in the School of Computer Science and Technology, Anhui University, Hefei, China. His research interests include name disambiguation in patent datasets.
